

CONTEXT SUMMARY

What DataMaster is and what it changes

DataMaster is a prototype control layer for government integrations. It gives downstream applications a stable set of canonical concepts, such as **business.nib**, while authoritative agencies remain owners of their records and API contracts.

CORE THESIS

Reuse already verified government records where policy and integrations allow, discover constrained adapters for legacy systems, and preserve downstream stability when upstream APIs evolve. **AI proposes; deterministic checks and humans approve.**

THE BATAM PERMIT STORY

PT Selat Niaga Makmur previously completed a BP Batam land-allocation workflow. A later logistics-permit workflow requests identity and legal records the government already holds: NIB, NPWP, company deed, director identity, and land information.

The applicant still supplies genuinely new information, including warehouse-control evidence, warehouse plans, and the requested logistics activity. DataMaster does not invent or autofill application-specific documents that no authoritative source already possesses.

JUDGE JOURNEY

01

Reuse

Resolve verified records with source provenance.

02

Onboard

Scan a legacy Python repository and review a constrained adapter.

03

Detect

Diff OSS v1 and v2 and identify affected consumers.

04

Approve

Test the mapping, update DataMaster, and prove the permit still works.

DataMaster updates its internal view - not the upstream repository

PRECISE BEHAVIOR

When an OSS contract change is approved, DataMaster updates its own semantic registry and adapter mapping, then regenerates **DataMaster-facing internal documentation** from the new OpenAPI contract. It does not edit, commit, or propose API documentation changes back to the OSS source repository.

WHAT IT DOES

- + Reads old and new OpenAPI contracts
- + Diffs paths, parameters, and fields
- + Finds affected canonical concepts and consumers
- + Proposes semantic field mappings
- + Updates the approved internal adapter and registry
- + Regenerates internal DataMaster docs

- Does not modify the upstream API implementation
- Does not commit to the upstream repository
- Does not open a documentation pull request
- Does not replace the upstream OpenAPI contract
- Does not apply AI suggestions automatically
- Does not change the permit application's contract

APPROVED CHANGE PIPELINE

IMPLEMENTED PROTOTYPE BOUNDARY

Stable downstream contract	POST /api/resolve with canonical concepts such as business.nib
Internal approved state	state/semantic_registry.json and JSON-backed proposal history
Internal generated docs	generated/docs/oss.md, derived from the approved OpenAPI contract
Upstream contract fixtures	contracts/oss-v1.openapi.json and oss-v2.openapi.json remain source inputs

BOTTOM LINE

The upstream repository remains responsible for its API and OpenAPI contract. DataMaster consumes that contract and safely maintains its own dependency knowledge, mappings, adapters, provenance, and internal documentation.
